of Callfornia Hadiation Laboratory at Barbaley has cumpleted a study on the effect of X-rays on extent retime. Particularly the visual response to small chase of X-rays was examined. Rescursional wave and first stimulus and the simpletedon and recovery after small chase of X-rays. It was found that absoluted a response could be measured on the retima after 0.6 resitions, that during empowers to X-rays the sensitivity to light was rechood, and that recovery of the retima after at X-ray stimulus was aloser than after a light stimulus. This recovery phenomenon inclusion that the effect is to a large extent reversible and the phenomenon is one of the smallest reversible restrict being with penetrating reclations.

Biological Synthesis-Fatty Acids. (UNCLASSIFIED) Research at the University of California at Los Angales includes a project on the mechanism of metabolism in animals with respect to Satty acids in the body. It has been demonstrated for the first time that an "essential" fatty acid can be synthesized in the animal body. This "essential" acid—areanichmic—contains twenty carbon atoms. Synthesis was accomplished from carbonyl labeled acetate and a compound containing sighteen carbon atoms. Further studies will be undertaken to elucidate the physiological eignificance of this reaction.

ment of mice with p-emisopropiopioscose (an agent producing a pro-nounced hypoxia) or gluthathices emerted a mested protective effect against total-body & radiation. A negligible degree of protection Biological Effects of Redistion. (UNCLASSIFIED) At Los Alemos Bolantific Laboratory, experiments have been undertaken to determine the biological effects of total-body I radiation in mice. Pretrest ation (thermal neutrons as found when mice so pretrested were exposed to thermal column radiplus comes contentrant). to determine Protrest-

It is tentatively suggested that the lack of effect of these agents against thermal column exposure results from the fact that the majority of the ionizations are produced along a short track and that under these conditions cartain produces produced by the ionization of water can be formed independently of malecular express.

On the basis of the data reported it appears that agents which are protective against one type of loninging radiation may not be of value against all types and that tissue oxygen tension may play a role in producing the marked differences observed in the relative effectiveness of neutrons and X-rays in various tissues.

Resistion Effects on Mortality, (UNCLASSIFIED) The effects of whole body irradiation of male rate on mortality among their off-spring is being studied by the ABC-University of Tempesses research group. Hale rate were exposed to 300 rountgens of games rays from a Cobelt 60 source, or to X-rays from 250 KVP. The irradiated males were subsequently mated to virgin families. The programt femiles were sacrificed, and it was found that the fostal death rate showed an increase in comparison with mon-irradiated controls. The per cents of deaths for the various groups were:

Control group...... 5.16 per cent Comme-ray exposure... 19.37 per cent X-rays (250 KVP)..... 19.92 per cent

After 60 days the same male animals were used in repeating the experiment. The values obtained after sacrifice of the second group of pregnant females were 7.39 per cent for gassa exposure and 8.19 per cent for I-rays. This does indicate a period of recovery and may be due to dominant lathal sutations induced during exposure in the more mature testis cells.

Research in Photosynthesis, (UNCLASSIFIED) At Oak Ridge National Laboratory, recent information has been reported in connection with the activity of light energy in photosynthesis. It has been known for some time that grown plants fluoresce and that the fluorescence is the back reaction from excited chlorophyll which has absorbed light. When the lights are turned off of a plant, the fluorescence ceases in less than 10° seconds and is felt to represent the reversibility of the first step in light absorption by chlorophyll, namely, the formation of excited chlorophyll. Investigations have shown that there is also a much weeker light emission from the dark plant which lasts for some seconds after the plant is placed in the dark. The emission spectrum of this delayed weak light has been shown to be the same as the

CEMINITY IMPORTATION

-3-

fluorescence of chlorophyll. The data indicate that the delayed light emission represents the reversal of the first several steps in photosynthesis, the light ultimately coming only from the reversal of the first step.

Industrial Health

Rediction Instruments Program

- 1. Special Electronics Development Program. (USCLASSIFIED)
 The Steering Committee for the Electronics Development Program held
 a meeting at Argenne Mational Leboratory on May 11, 15, 1953. In the
 light of technical developments and the increasing demand for special
 electronic requirements of various ABC installations, recommendations
 were made to accelerate studies in (a) basic research on the phenomena
 of photoelectric emissions (b) research development of new photoelectric and secondary emissive surfaces; (c) improvement of photomultiplier transit spread characteristics; (d) development of large
 photo-cathods multiplier tubes up to 30° and 36° in dismeter; and (e)
 model shop fabrication of test quantities of tubes developed under the
 program. Research projects will be undertaken with Notre Dame
 University, the Radio Corporation of America, and the Allen B. DuMont
 Leboratories.
- 2. Review of Standardisation Problems, (UNCLASSIFIED) The accelerated pace of instrument development in the standardisation energy field inevitably introduces a number of problems in standardisation requirements. The Radiation Instruments Branch maintains close limits with the many organizations of government and private industry and serves as representative or advisory member on numerous constitutes which formulate recommendations to further standardisation of basic instrumentation and component parts pertinent to technical operations.

Righlights of some of the problems recently considered and action taken are given:

a. In the nuclear instrumentation field, one of the major problems lies in the production of various types of electrical cable connectors on semufacturers' equipment which serve similar functions. At a recent meeting of the Radio-Talevision Messifacturers Association Sub-Committee on Ruclear Instrumentation, the frequency of use of various commenter-type cables in AEC laboratory-built mealess measurement equipment was discussed. A tabulation was given which showed that two particular types of commenters (identified as the IPC 27000 and IPC type RH series) were

in predominant use for high voltage service, and for low voltage circuits the IPC 1500 was used. The introduction of this problem led to the recommendation by the Sub-Countitee that the standard type of high voltage connector on commercial nuclear measurement equipment would be of one type, namely type-HH series connector. The type UHF (IPC 11875) connector with teilon insert was selected as the standard type for use in low voltage circuits. Although such problem areas may not appear significant, the recommendation represents a stap forward. The efficacy of technical operations is dependent on the flexibility of interconnecting equipment, and standardisation procedures are important in reducing costs and labor. Although

GLIOTES

sects in this field, meetings are hald periodically with the Office of Basic Instrumentation of the Mational Bureau of Standards to coordinate plans for research studies. Mathoral Bureau of the Department of Defense who are principal consumers of special instruments and devices necessary in technical operations. This program is designed to establish a cohesiveness of purpose and effort in basic instrumentation research projects at the various laboratories of interested groups, and to aliminate unnecessary duplications of effort. This work is of benefit to all fields of science in which problems of instrumentation are related. Recommendations for the cowing year were made to emphasize studies on oritical surveys of currently used instruments, or instrumentation techniques; theoretical or experimental evaluation of new applications of physical principles in measurement and control; and theoretical analysis in various fields of measurement control and handling of data.

General

Fall-out Phenomens—Hashington, D.C. (In the storic detonation of May 25 at Nevada, the trajectory of the path of the storic cloud for the 18,000-foot level showed that it passed over Mashington, D.C. on May 25. On the same day, a hallshower occurred in the Northwest section of the city which produced hallshower occurred in the air at the time of the hallshower recorded at the Mayal Research Laboratory was the highest yet noted here, i.e., 6 x 10⁻³ microcuries per cubic meter averaged over 21 hours, with the activity remaining in the air in significant amounts for about five hours. The maximum permissible concentration is 1.0 microcuries per cubic meter averaged over 24 hours.

DECEDIATED

The hallstones were collected and melted down to examine the water for radioactivity. The activity measured on the third day after detonation by the Maval Research Laboratory was 2×10^{-11} microcuries per cubic continuous, and by the Division of Biology and Medicine, 3.2×10^{-12} and 1.6×10^{-12} microcuries per cubic continuous. These may be compared to the maximum paradesible concentration of 5×10^{-12} microcuries per cubic continuous for drinking water, which is based on the assumptions that all of the water intake will be from the same source and consumed at this concentration continuously. Of course, the activity for the hallstones quoted above will drown rapidly according to well—established principles.

Data have also been obtained by the Naval Research Laboratory showing that activity in the center region of the helistones was approximately five times greater than in the peripheral region.
