

Colorado Department of Health
Nevada Test Site - Nuclear Venting

Radiological Surveillance

On December 18, 1970, the Colorado Department of Health was notified by the Environmental Irradiation Center (EIC) and the State Radiological Health Laboratory (SWRHL), Las Vegas, Nevada, that a release of radioactive material to the atmosphere which occurred at the Nevada Test Site (NTS) during a nuclear device detonation.

Upon this notification, the Department's Radiological Health Staff activated the various radiological surveillance and sampling programs to provide adequate monitoring of the situation.

Four air sampling networks were set up initially. These included air sampling stations used for the initial detection of fallout from the 1968 U.S. Atomic Energy Commission-Rocky Flats surveillance network; the Department's own network (DN) and the NTS-EPA network. A total of 164 air samples were taken from 45 air sampling stations throughout the State. Of these, 100 samples were collected by the Department and 64 samples were collected by SWRHL for their determinations.

A total of 164 determinations have been made on the 68 samples retained by the Department. The results of these determinations indicated no deviation from sample concentrations expected prior to the "venting".

The Department's milk sampling network, consisting of 10 sampling sites, were collected from January 1970 through December 1970. Determinations on these samples are still in progress. No increase in environmental radioactivity was observed prior to the "venting".

In conferring with representatives of the State of Colorado and submitting samples to the EIC, no increase in environmental radioactivity due to the venting was anticipated.

Individual air sample results, determined by the Department, are tabulated in the attached table. The beta (β) concentration is expressed in picocuries per liter (pCi/l) or picocuries per minute (pCi/m^3). The alpha (α) concentration is expressed in picocuries per liter (pCi/l) or picocuries per minute (pCi/m^3). All milk samples had non-detectable levels of radioactivity due to the naturally-occurring Potassium-40 which remains constant.

In summary, radioactive material released during the "venting" on December 18, 1970 was not detected in either the air or milk samples.

On the 68 samples retained by the Department, 16 air samples collected prior to the "venting".

All the air samples collected in December showed no increase in environmental radioactivity above that observed prior to the "venting".

Individual air sample results, determined by the Department, are tabulated in the attached table. The beta (β) or Alpha (α) concentration is expressed in picocuries per liter (pCi/l) or picocuries per minute (pCi/m^3). All milk samples had non-detectable levels while the naturally-

* Two samples were taken per day, one for particulates and one for materials precipitated from the charcoal. Samplers manned by State personnel made the determinations and determinations made by Battelle Seattle Research Center. Individual sample results are not available at this time.
